## **Laboratory work N1**

Course: **Programming**

Theme: **Linear programs. Working with mathematical functions.**

Student: Igors Oļeiņikovs

Student code: 93642

Group: 4501BTA

Riga  
2025

## Contents

1. Laboratory work task .....	3
2. Individual task .....	3
3. Algorithm .....	4
4. Source code .....	5
5. Running program example .....	6
6. Testing .....	6
7. Conclusions .....	7

## 1. Laboratory work task

Create an algorithm that calculates values  $z1$  and  $z2$  by formulas given in individual task.

## 2. Individual task

Individual task number is being defined by formula: **taskNr = studentCode % taskVarCount**

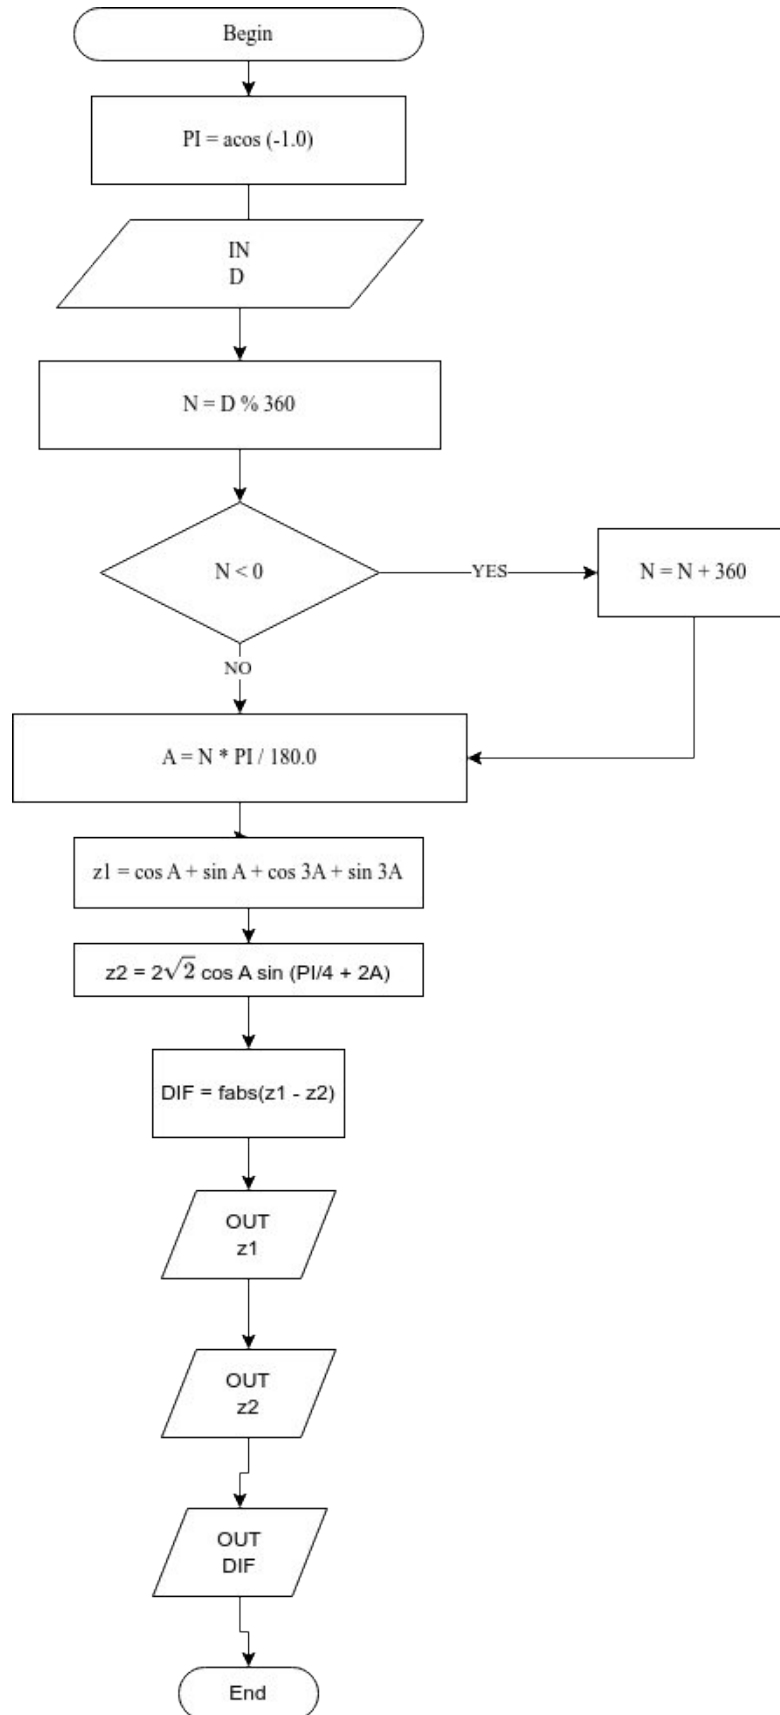

$$93642 \% 20 = 2$$

$$Z1 = \cos \alpha + \sin \alpha + \cos 3\alpha + \sin 3\alpha$$

$$Z2 = 2\sqrt{2} \cdot \cos \alpha \cdot \sin \left(\frac{\pi}{4} + 2\alpha\right)$$

Create a console application in C/C++ based on created algorithm that calculates  $z1$  and  $z2$  by given formulas. Output calculation results to a screen (if calculations are made correctly then  $z1$  and  $z2$  should be equal, difference is allowed in last digits after point).

### 3. Algorithm

Pic. 1. Algorithm data flow

#### 4. Source code

```
#include <iostream>
```

```
#include <cmath>
```

```
int main(void)
```

```
{
```

```
    int          input_degr;
```

```
    int          normalized_input;
```

```
    double       alfa_rad;
```

```
    double       z1;
```

```
    double       z2;
```

```
    double       diff;
```

```
    const double PI = acos(-1.0);
```

```
    std::cout << "Task Nr " << 93642%20 << std::endl;
```

```
    std::cout << "Enter angle in degrees: ";
```

```
    std::cin >> input_degr;
```

```
    normalized_input = input_degr % 360;
```

```
    if (normalized_input < 0) normalized_input += 360;
```

```
    alfa_rad = normalized_input * PI / 180.0;
```

```
    z1 = cos(alfa_rad) + sin(alfa_rad) + cos(3 * alfa_rad) + sin(3 * alfa_rad);
```

```
    z2 = 2 * sqrt(2) * cos(alfa_rad) * sin(PI / 4 + 2 * alfa_rad);
```

```
    diff = fabs(z1 - z2);
```

```
    std::cout << "Z1 = " << z1 << std::endl;
```

```
    std::cout << "Z2 = " << z2 << std::endl;
```

```
    std::cout << "Diff = " << diff << std::endl;
```

```
    return (0);
```

```
}
```

## 5. Running program example

```
altin@G3: ~/TSI
altin@G3:~/TSI$ g++ -Wall -Wextra -Werror Lab_N1.cpp
altin@G3:~/TSI$ ./a.out
Task Nr 2
Enter angle in degrees: 160
Z1 = -0.231647
Z2 = -0.231647
Diff = 5.82867e-16
altin@G3:~/TSI$
```

Pic. 2. Running program example

## 6. Testing

Table 1

Input	Z1	Z2	Difference
-360	2	2	0
-90	3.33067e-16	3.67394e-16	3.43271e-17
-45	-1.41421	-1.41421	1.33227e-15
-705	2.63896	2.63896	4.44089e-16
0	2	2	0
45	1.41421	1.41421	4.44089e-16
60	0.366025	0.366025	1.66533e-16
90	-2.22045e-16	-1.22465e-16	9.95799e-17
180	-2	-2	0
200	-2.64774	-2.64774	4.44089e-16
1300	-1.77486	-1.77486	2.44249e-15

## 7. Conclusions

Algorithmic flow:

- Normalize input\_degr into  $[0, 360) \rightarrow \text{normalized\_input}$ . (Helps reduce rounding errors)
- Convert to radians:  $\text{alfa} = \text{normalized\_input} * \text{PI} / 180$ .
- Compute two mathematically-equivalent expressions:
- $z1 = \cos(\text{alfa}) + \sin(\text{alfa}) + \cos(3\text{alfa}) + \sin(3\text{alfa})$
- $z2 = 2 * \sqrt{2} * \cos(\text{alfa}) * \sin(\text{PI}/4 + 2*\text{alfa})$
- Compute  $\text{diff} = |z1 - z2|$ .
- Print  $z1, z2, \text{diff}$ .

Machine epsilon (double precision):  $\text{eps} \approx 2.22\text{e-}16$ . Any single floating-point operation can introduce relative errors on the order of  $\text{eps}$ .

Each trigonometric evaluation ( $\cos, \sin$ ) returns an approximate result with error roughly  $O(\text{eps})$  relative to the true value. The subsequent arithmetic (adds, multiplies) accumulates and propagates those errors.

When the true result is 0 (for example at  $\text{alfa} = 90^\circ$  both expressions are exactly 0 analytically), the computed terms (e.g.,  $\cos(\text{pi}/2)$ ) are tiny non-zero values of  $\pm O(\text{eps})$ . Summing several small terms with mixed signs can leave a residual of order a few  $\times \text{eps}$  (e.g.,  $-2.22\text{e-}16$ ), and two different algebraic forms ( $z1$  vs  $z2$ ) do different sequences of operations  $\Rightarrow$  different rounding paths and slightly different residues (e.g.,  $-2.22045\text{e-}16$  vs  $-1.22465\text{e-}16$ ). Their difference is about the same order as  $\text{eps}$  ( $\approx 1\text{e-}16$ ).

Operation count matters:  $z1$  computes 4 trigonometric calls + 3 additions;  $z2$  uses fewer or different operations (including a multiplication by  $\sqrt{2}$  and a single trig). Different operation trees produce different rounding errors.

Given expressions are mathematically identical and can be mutated to one from other with trigonometric transformations.

**Conclusion**: A difference is expected and is numerical noise, not a correctness bug.
